

BECS Security Module

From CVE data to priorities in minutes – Built for networks where security can't rely on manual checks

BECS Security Module

Automatically match CVEs to your network

BECS Security Module brings a new approach to network vulnerability management as the first solution to automatically match network hardware and firmware against known CVEs across multi-vendor environments. It gives you one place to identify relevant vulnerabilities, understand what may be affected and prioritise where your attention is needed.

Turn days of manual research into minutes

Reviewing CVE databases is only the beginning. Manually working out which CVEs are relevant to your network, matching them to your hardware and firmware, keeping track of the findings and deciding what needs attention first can sometimes take hours, or even days.

BECS Security Module automates that process. Vulnerability data is retrieved twice daily from one of the world's largest CVE databases and automatically matched against your registered network infrastructure.

Instead of searching, cross-referencing and maintaining separate lists, you can quickly see known CVEs relevant to your network and focus your time on reviewing and prioritising the findings.

One view across your network environment

Whether your network is built around a single vendor or multiple vendors, BECS Security Module brings relevant CVE information together in one place.

You can see which known CVEs affect your registered devices, review and sort the findings, and quickly understand where vulnerabilities exist across your network infrastructure.

This means less time spent finding and organising vulnerability information, a lower risk of overlooking known CVEs and better information for deciding what requires attention first.

Built for networks where security can't rely on manual checks

BECS Security Module is designed for telecom operators and other organisations managing network infrastructure where keeping track of known firmware vulnerabilities is an ongoing responsibility. As networks grow, and the number of devices and firmware versions increases, manually checking and maintaining CVE information becomes increasingly difficult to manage.

From visibility towards remediation

BECS Security Module starts by helping you identify and more easily prioritise known vulnerabilities. Used together with BECS Streamlined Module, it enables fast and secure firmware upgrades, taking you from vulnerability identification towards remediation.

Start with Security Module

Already using BECS? Security Module adds vulnerability intelligence directly to your existing network management environment.

New to the BECS Network Orchestration platform? You can start with Security Module without undertaking a full BECS implementation. This gives you a lighter way to introduce automated vulnerability monitoring to your network without implementing the wider capabilities of the BECS platform.

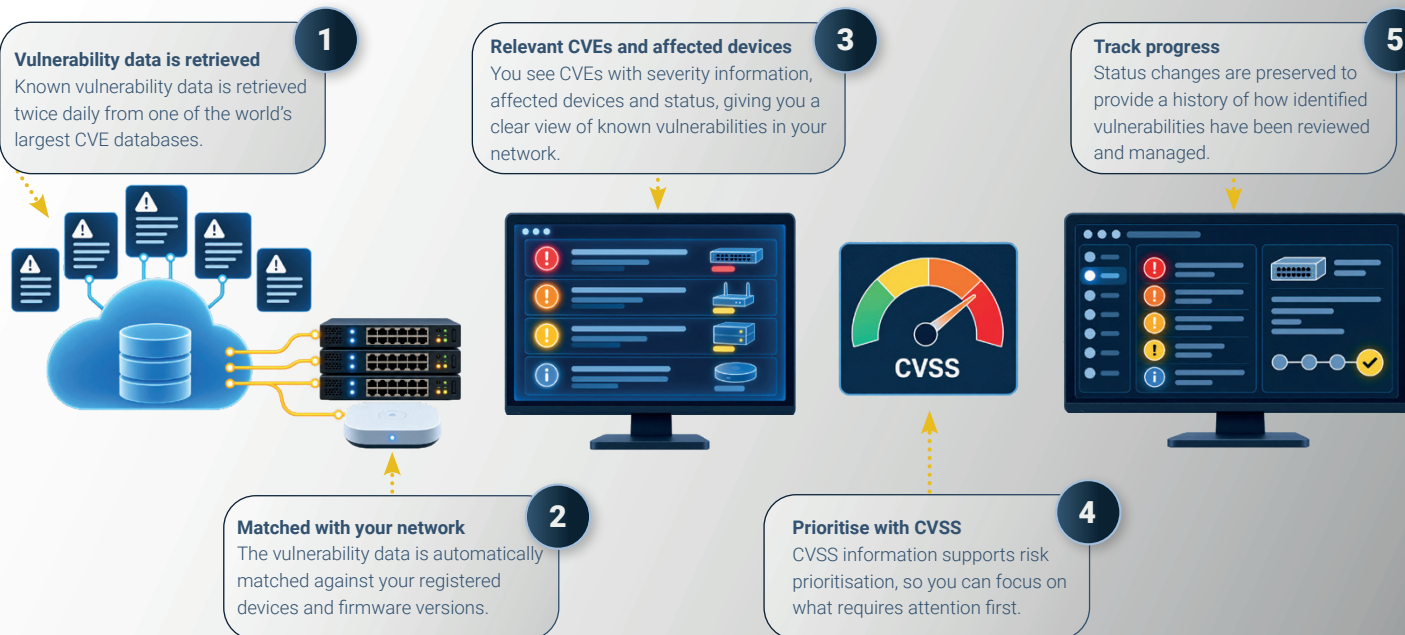

How the BECS Security Module works

BECS Security Module brings vulnerability intelligence together with information about the devices and firmware running in your network.

Known vulnerability data is retrieved and matched against your registered devices and firmware versions. Relevant findings are then presented together with CVE and severity information, affected devices and status, giving you a clear view of known vulnerabilities in your network.

If you already use BECS Atlas, Security Module works with the network information in your existing environment. If not, you can still use Security Module to monitor and match vulnerability intelligence against your network without implementing the wider orchestration capabilities of BECS Atlas.

CVSS information supports risk prioritisation, while status changes are preserved to provide a history of how identified vulnerabilities have been reviewed and managed.
